Number 9

PROGRAMMABLE KEYBOARD STATUS A meeting of the FCC is scheduled around Sept.15, at which time the TI petition will be discussed. Bally currently feels that regardless of the decision, they will not be able to have a keyboard in production by the end of the year.

SURVEY The subscriber survey has resulted in a fair turnout of respenses from those interested in a keyboard/memory addition, and a number of useful suggestions as well. What is evolving now is a unit that could have 16K of RAM that would accept a cassette input of the operating program, be it BASIC, COBOL, FORTRAN, or whatever(your choice) which would be loaded in about 2 minutes at 1200 baud (while the picture tube was warming up), plus an additional 8 or 16 K of onbeard RAM for the user's programs. There would be space to add more RAM by chip insertion(especially the 8K version), plus connectors to allow outside memory addition. Serial and parallel ports would be available for the addition of other peripherals. Those who responded to the survey will be kept up to date.

BLACK BOX GAME enclosed is a sort of Battleship game where the computer hides some "atoms" in a grid and you have to locate them. Use the diagram for clues.

TUTORIAL ON SOUND adds more material from Chuck Thomka to last issue's discourse

SLOT MACHINE CORRECTION requires the addition of a comma to the very end of line 1515 to stop the scrolling.

<u>RIG LETTERS</u> continue to interest subscribers. Dennis Sprague modified the p.45 program to write double size letters on command - the poke-ing is done automatically. Refer to the program on p. 45 and retain lines 9 thru 60, and line 120. Replace the rest with: 65 A = 20190

```
70 K = KP

80 IF K = 13 GOTO 100

90 $(A) = K; A = A+1; GOTO 70

100 $(A) = 0

105 CLEAR

110 CALL (B); GOTO 65
```

Dennis writes " 65 starts the display area, 100 shuts offthe display if a zero is encountered. The ASCII values of K get poked into the display area 8 bits at a time."

With the above, enter and RUN the program. The just key in whatever letter, number, character that you wish to see, punch GO, and there it is, twice as big as life.

AMERICAN CONCERT FREQUENCIES chart has been prepared by Robert Hood, along with the closest Bally frequency: (all in Hertz)

Note	Standard	Bally	Note	Standard	Bally
C	261.7	262	G	392	392
C#	277.3	277	G #	415.2	415
D	293.7	294	A	440	440
Eb	311.1	311	Bb	466.1	466
E	329.7	330	В	493.9	494
F	349.2	349	G	523.3	524
F#	370.1	370		J-J-J	<i>J</i> ~ .

In addition, Bob has furnished a program based on the equations of p.64 to solve for frequencies or tone register values, and this is found on p.70.

BANGMAN CORRECTION COMMENT by Ernie Sams indicates that perhaps Rory Wahl has a defective logic chip if Rory's correction in the last issue is needed to make the program work. Ernie writes:

"Rory suggests that the line should read:

2000 E=E+1; IF E=9 GOTO $9\phi\phi\phi$; IF Q=1 GOSUB $96\phi\phi+(Ex1\phi)$

Q is a flag that is set to either \emptyset or 1. If it is set to \emptyset it sends the program to the man drawing routine at 9600, 9610, 9620, etc.

E is a counter that is to be incremented ONLY if the guess is wrong. It is NOT to be incremented if the guess is correct or if the letter has been previously used. So the portion of the program line, E=E+1, must follow the IF statement. Now, if the 'IF' portion of the IF E=9 GOTO 9000 statement is not satisfied the program defaults to the next numbered program line. The way Rory proposes, E would be incremented each time a guess is made, right or wrong. The program would never reach the man drawing routine statement because it can't go past the first IF statement until E=9 at which time the program goes to 9000, draws the gun and shoots the man that never gets drawn on the screen.

So line 2000 MUST remain exactly as was originally written on the program will

So line 2000 MUST remain exactly as was originally written or the program will not work as intended:

2000 IF $Q\neq 1$ GOSUB 96pp + (Ex1p); E=E+1; IF E=9 GOTO 9pp p

I have included all of Ernie's discourse as I felt that it would be of interest as a tutorial in why things are done in a certain way.

BOB HOOD's program to convert frequecies to register values and vica versa:

TUTORIAL - SOUND SYNTHESIZER, Part 2 by Chuck Thomka

Whenever RESET is pushed, the &(16) to &(23) registers are set to fixed values. (This sort of thing is called DEFAULT) This also happens at POWER TURN ON. &(16) is set to 71, and &(17) through &(23) are set to zero.

Since pushing most keys on the keypad will generate a sound, one of the voices must be used. This means that since most keys have unique tones when pushed, they must be loading unique values into one or more of the registers. The voice used is the 'A' counter. Each key, when pushed, puts a value into the &(17) register that the 'A' counter will count up to. It will also put value 15 into the &(22) register, that will adjust the 'A' volume to its maximum so that the resultant frequency can be heard. At the end of the time of outputting the tone, the &(17) and &(22) are both put back to zero.

At anytime that the computer is stopped, the &(16) register will be set to 71, and &(17) and &(22) will be set to zero. This may affect some results of sound effects in programs where you want those registers to be left at some other values. All the other registers will be as they were last adjusted to, so remember this if you still have a tone or noise remaining after the computer has stopped.

Later in this article is a table of all the sound generating keys, their &(17) values, the resultant frequencies, and any special notes about them. (p.73)

The keys that do not generate sounds are $\frac{1}{4}$, x, +, and -. These keys will modify the sounds created by the other keys if the modifying keys are used just prior to the normal sound keys.

The divide key $(\frac{1}{4})$ will make the sound one octave lower in frequency than normal. This is done by temporarily making the master counter &(16) count twice as far. So while &(16) is normally at 71, for this one note it will be set to 143. As soon as the note has finished, &(16) will again return to 71 unless the next note is also preceded by a $\frac{1}{4}$.

The multiply key (x) will make the sound one octave higher in frequency. This is done by making &(16) equal 35 for the time the concerned note is sounding, at the end of which the &(16) will again return to 71.

The plus (+) and minus (=) keys are only used in conjunction with the numbers 1 through 7. This was arranged so that the plus and minus sign would be meaningful in playing musical sharps or flats in the Bally-mentioned 3 octave musical scale.

Another thing to mention is the "Note Timer" or NT. For each number of NT the notes played will be approximately 17 milliseconds long. An NT= \emptyset results in no sound, while the maximum value of NT=255 results in about a 4.335 second note. (0.017 x 255 = 4.335)

The \emptyset is used to extend the duration of a played note by taking the note timer and increasing it an additional NT quantity for each \emptyset following the note to be heard. For example, say we are to play a note while NT=10, and that this note is followed by 3 zeros, the resultant NT will be 40. After playing that modified NT, the NT will again return to normal (10 in this example) until called upon again.

A funny thing about this method of extending the duration of a played note is that you still cannot play any note longer than 4.335 seconds. This is because if you had a note timer extended by way of using zeros after a printed character, and it would result in an NT>255, the final result would probably be less than 255. To explain what I mean, you have to know about binary numbers and that the NT register is only 8 bits wide. If, for example, we had an NT of 50 and that some program that we are running is to print a character followed by 5 zeros, we would expect a temporary NT result of 300 (1+5=6, 6x50=300) but an 8 bit register's maximum bit count is only 255 while a binary conversion of

decimal 300 requires 9 bits (1 0010 1100). The result is that only the least 8 bits (0010 1100) will be loaded into the NT register, so NT will temporarily be 44. This you see is a lot shorter than we had at first expected and even shorter than the normal NT of 50.

TUTORIAL-SUBROUTINES

If you have a process that you want to have repeated a number of times, it is convenient and memory-saving to use the technique called SUBROUTINE, which requires the commands GOSUB and RETURN. I recently received a short program from Bret Dabel and Vince Garzoli that has this situation, and I thought that it might be of interest to all to show how a program can be modified this way. The program as it arrived is:

```
10 A=RND(32000)
20 INPUT "PLAYER $1 GUESS:" E
30 IF A=E PRINT B, "IS RIGHT"
40 IF A>B PRINT "MORE"
50 IF A<B PRINT "LESS"
60 INPUT "PLAYER $2 GUESS:" B
70 IF A=B PRINT "MORE"
90 IF A>B PRINT "MORE"
90 IF A\B PRINT "MORE"
100 IMPUT "PLAYER $3 GUESS:" B
110 IF A\B PRINT "LESS"
140 IF A\B PRINT "MORE"
130 IF A\B PRINT "MORE"
130 IF A\B PRINT "LESS"
140 IMPUT "PLAYER $4 GUESS:" B
150 IF A\B PRINT "LESS"
150 IF A\B PRINT "MORE"
170 IF A\B PRINT "LESS"
180 IF A=B GOTO 10
```

To utilize the SUBROUTINE command, we make the process to be repeated into a set of generalized statements and end them with the RETURN command. Then whenever you wish to perform the process, you direct the machine to the proper location with the GOSUB command, and when the machine does its job, it reads RETURN which tells it to go back to where it left the main program and pick up the next line number. This last statement is quite important.

As an example, lets review the Guessing Game program. We see that the A and B comparisons

occur four times and so we can make a subroutine of them, giving them a set of line numbers away from the main program, as: 500 IF A = B PRINT B, "IS RIGHT"

510 IF A>B PRINT "MORE"
520 IF A<B PRINT "LESS"
530 RETURN

The program then reads:

```
10 A=RND(32000)
20 INPUT "PLAYER #1 GUESS:" B
30 GOSUB 500
40 INPUT "PLAYER #2 GUESS:" B
50 GOSUB 500
60 INPUT "PLAYER #3 GUESS:" B
70 GOSUB 500
60 INPUT "PLAYER #4 GUESS:" B
90 GOSUB 500
100 IF A=B GOTO 10
110 GOTO 20
500 IF A=B PRINT B, "IS RIGHT"
510 IF A>B PRINT "MORE"
520 IF A<B PRINT "LESS"
530 RETURN
```

If by chance you have written the subroutine at lines 500 - 530 but later you have added so much program that 500-530 will be buried in the program length, you will have a problem. As the computer completes line 490, it will search for the last value of A and B and perform the comparisons asked for in lines 500 through 520 (would you want that, then?) but it will HOW? when it gets to 530 because it is not in a subroutine mode and has no place to return to. To avoid this, you jump around the subroutine, in our case with a 490 GOTO 540. Since this is a legitimate operation, it means therefore that the subroutine could actually

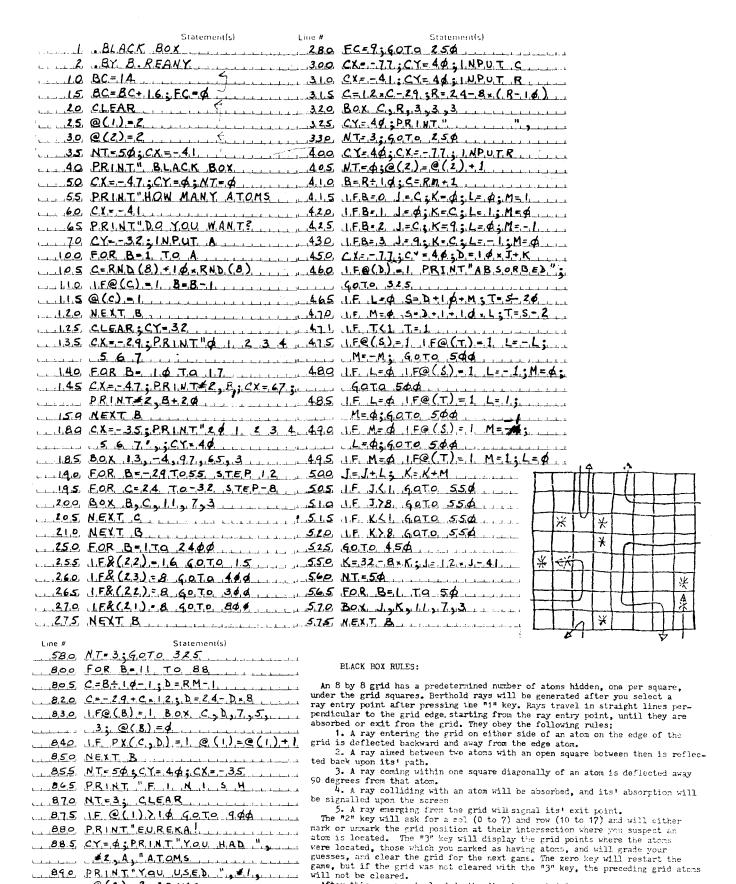

be placed anywhere within the program, and a suitable jump statement added.

Nesting of subroutines is possible. By this we mean that once you have gotten into the subroutine loop, you could have another subroutine called. The machine would perform the second subroutine and RETURN to the next line number of the first subroutine, and on its completion, go back to the main program. I believe that four such 'nests' are possible in the Bally BASIC, but one has to be very careful that each subroutine loop is completed - there cannot be any open loops. Diagramatically, the quessing game looks like this:

40 2500 +500 60 F\$ 500 7 80 ~ 500 7100-710 10 510 50-110 - 20 510 510 70 90 -510 20 520 520 520 520 30 **630** 530 530 530

REVIEW of programs has been suggested by some subscribers, who are concerned about purchasing a 'pig in a poke'. If someone else is willing to do a critical review of a program that some advertiser is also willing to submit, I will get the two parties together and accept the review for publication. The opinions will be the reviewers, not mine.
